Rendezvous recanalization of a postoperative coloanal anastomotic dehiscence with a lumen-apposing metal stent

LAMSs have been successfully used for the recanalization of complete colorectal anastomotic obstructions [1, 2]. However, there are no reports of using LAMSs in the treatment of coloanal anastomotic dehiscence.

A 51-year-old man with a rectosigmoid tumor underwent low anterior resection. His surgery was then complicated by leakage, which was treated by proctectomy, coloanal anastomosis, and creation of a diverting ileostomy. On follow-up sigmoidoscopy, the anastomosis appeared to have dehisced and no lumen to the proximal colon was identified. Therefore, a rendezvous approach was planned for the treatment of coloanal anastomotic dehiscence.

An upper gastrointestinal (GI) endoscope was advanced transanally to the coloanal anastomosis, while a pediatric colonscope was advanced towards the anastomosis through the loop ileostomy (Fig. 1). With the use of fluoroscopic guidance and transillumination, the dehiscent coloanal anastomosis was identified. A guidewire was advanced in an antegrade direction and was captured from the anus. A $15 \times 10$-mm LAMS was then inserted over the wire from the anal side and successfully deployed across the anastomosis (Fig. 2 and Fig. 3; Video 1).

The patient was discharged home in good condition 1 day after the procedure. After 2 months, a flexible sigmoidoscopy was carried out, in which the stent was removed with a forceps. The upper GI endoscope was advanced to a point proximal to the anastomosis, which was noted to be widely patent (Fig. 4). The stent was then reloaded into the therapeutic upper...
GI endoscope and redeployed across the anastomosis to ensure the area remained patent. After 4 months, the stent was removed following ileostomy reversal. The patient continues to do well after 3 months of follow-up.

In conclusion, treatment of postoperative coloanal anastomotic dehiscence using a LAMS placed via the rendezvous technique is feasible and effective.
