

Underwater endoscopic submucosal dissection for a duodenal neuroendocrine tumor using pocket creation and ring-shaped thread countertraction methods

► **Fig. 1** Endoscopic image showing a duodenal neuroendocrine tumor at the superior duodenal angle.

A 55-year-old man was previously diagnosed with a neuroendocrine tumor (NET) following biopsy of a duodenal submucosal tumor. He was referred to our hospital for treatment of the lesion. Esophagogastroduodenoscopy revealed a submucosal tumor measuring 9 mm in diameter at the superior duodenal angle (► **Fig. 1 a**). Endoscopic ultrasound (EUS) revealed a uniform, low echogenic tumor of 8.6 mm in the submucosal layer. Underwater endoscopic submucosal dissection (uESD) [1] using the pocket creation method (PCM) [2] and ring-shaped thread countertraction technique [3] was performed (► **Fig. 2**; ► **Video 1**).

First, hyaluronic acid was injected into the submucosa around the lesion, and an incision of about 1.5 cm was made in the mucosa on the oral side of the lesion. The submucosa below the lesion was dissected using the water-immersion PCM. After a circumferential mucosal incision had been created around the lesion, a 10-mm ring thread was attached to the oral side of the lesion by an endoclip. The other end of the ring thread was then attached, by a second endoclip, to the normal mucosa opposite the lesion (► **Fig. 3 a**). The lesion was completely resected en bloc with no adverse events (► **Fig. 3 b**). Histologi-

cal examination confirmed a gastrointestinal NET G1 with submucosal invasion (2460 μ m) (► **Fig. 4**). The vertical and horizontal margins were negative for tumor.

Duodenal NETs are rare; they represent 3.8% of all gastrointestinal NETs [4]. Endoscopic treatment may be performed for duodenal NETs measuring ≤ 10 mm in diameter and confined to the submucosal layer, without metastasis.

Common endoscopic treatments for duodenal NETs have included endoscopic submucosal resection with a ligation device, endoscopic mucosal resection

(EMR), and cap-assisted EMR [5]. However, these carry the risk of perforation and the possibility of positive vertical margins. A combination of these methods can allow en bloc resection of duodenal NETs more safely.
