

Clipping a gastric lesion before resection: not a contraindication for endoscopic submucosal dissection

► **Fig. 1** Endoscopic views showing: **a** a type 0-IIa lesion in the lesser curvature of the corpus with two metal clips that were placed during a diagnostic procedure; **b** submucosal fibrosis noticed within the clipped area during the endoscopic submucosal dissection procedure.

► **Video 1** A 0-IIa lesion with two metal clips placed during the diagnostic procedure was removed by endoscopic submucosal dissection. Submucosal fibrosis within the clipped area was noticed, but en bloc resection was achieved without complications.

► **Fig. 2** Macroscopic appearance of the en bloc resected specimen.

mucosal injection and circumferential incision were performed and ESD was then completed from the distal to the proximal side. Although submucosal fibrosis was noticed within the clipped area (► **Fig. 1 b**), en bloc resection was achieved without adverse events (► **Fig. 2**; ► **Video 1**). At the end of ESD, major vessels in the scar were prophylactically coagulated (Coagrasper Hemostatic Forceps; Olympus). No delayed complications were observed and the patient was discharged after 3 days. Histopathological analysis revealed a moderately differentiated adenocarcinoma with superficial submucosal invasion (<0.5 mm), without lymphovascular or perineural invasion, and with negative vertical/horizontal margins (► **Fig. 3**). Risk factors for difficult ESD of gastric lesions include larger size, middle- or upper-third location, and the presence of ulceration, submucosal fibrosis, or invasive cancer [1–3]. The technical implications of the presence of a clip within a gastric lesion have not been fully studied, but it is likely to add a degree of difficulty because of a fibrotic reaction in the submucosal layer and the potential risk of thermal injury by cutting adjacent to the clip. We consider that ESD of lesions carrying a metal clip may be a feasible and safe and that this should not be considered

A 53-year-old woman underwent an upper gastrointestinal endoscopy because of dyspepsia. A 15-mm, type 0-IIa lesion was identified in the lesser curvature of the distal corpus. After a biopsy was taken, a moderate hemorrhage occurred and two metal clips were applied (► **Fig. 1 a**). The histopathological result showed high grade dysplasia so the pa-

tient was referred to our department to undergo endoscopic resection. After proper multidisciplinary discussion and clear information on the expected technical challenges, endoscopic submucosal dissection (ESD) was planned and then performed using an insulated-tip knife (IT-knife 2; Olympus), with the patient under deep sedation. First, sub-
