Abstract: A new strategy for the synthesis of 3-methylene-2,3-di-hydro-1*H*-pyrazoles is presented by Ni-catalyzed oxidative cyclotrimerization of α-amino ketones. This unprecedented method allows three α-amino ketones to undergo sequential multiple deprotonations and deamination through two C–C bonds and one N–N bond formation cascade.

Key words: nickel, oxidation, cyclotrimerization, α-amino ketones, pyrazoles

The functionalization of α-amino carbonyl compounds is one of the most important tasks for biochemists or synthetic chemists because the α-amino carbonyl motif is a ubiquitous structural component of multitudinous natural products and biomolecules.[1,2] Despite the impressive progress in the field, the functionalization of α-amino carbonyl compounds remains challenging due to the presence of some highly reactive functional groups in them, such as an active α-C–H bond, a free N–H bond and a carbonyl group, often resulting in some competing reactions. To our knowledge, however, a method using the three functional groups for constructing new chemical bonds in one reaction has not been established.

Pyrazoles are important structural units found in numerous pharmaceuticals, agricultural chemicals and functional materials as well as valuable synthetic intermediates in organic synthesis.[3] Many elegant methods have been developed for their synthesis,[4–8] including, (i) the cyclocondensation of hydrazines with 1,3-dielectrophiles (1,3-dicarbonyl compounds or α,β-unsaturated aldehydes and ketones),[5] (ii) the intermolecular 1,3-dipolar cycloaddition of diazoalkanes and nitrilimines with unsaturated compounds (such as alkenes or alkynes),[6] and (iii) the introduction of substituents onto a pre-existing aromatic ring (often onto the nitrogen atom).[7] However, these methods suffer from the poor reactivity, somewhat limited substrate scope, and the potential hazardousness and detonation of the substrates; moreover, regio- and chemoselectivity are usually unsatisfactory in many cases. Therefore, the development of new strategies for the synthesis of functionalized pyrazoles is highly desirable. Herein we report a novel route to prepare pyrazoles by Ni-catalyzed oxidative cyclotrimerization of α-amino arylketones wherein sequential multiple C–H bonds cleavage, deamination and carbonyl isomerization take place to simultaneously form three C–C bonds and one N–N bond (Scheme 1).[8,9]

Our investigation began with the reaction of 1-phenyl-2-(phenylamino)ethanone (**1a**) to optimize the reaction conditions (Table 1). Gratifyingly, substrate **1a** could undergo cyclotrimerization with NiCl$_2$ in CH$_2$ClCH$_2$Cl at 80 °C, providing the desired product **2a** in 28% yield (entry 1). Encouraged by the results a number of other Ni catalysts were examined (entries 2–6). Extensive screening revealed that (C$_5$H$_5$)Ni(II)Cl(PPh$_3$) displayed the highest catalytic reactivity (entry 5). It is noteworthy that Ni(PPh$_3$)$_4$, a zerovalent Ni catalyst, also effected the reaction (entry 6). Interestingly, benzoic acid was found to favor the reaction: The yield of **2a** was enhanced to 75% when one equivalent PhCO$_2$H was added (entry 7). In light of the results, a series of other organic acids were subsequently evaluated (entries 8–11). While 4-cyanobenzoic acid could improve the reaction, the other acids, 4-methoxybenzoic acid, AcOH and PivOH, lowered the yield slightly. Gratifyingly, good yield was still achieved under O$_2$ atmosphere (entry 12). However, substrate **1a** was found to be inert under argon atmosphere (entries 13 and 14) as well as in the absence of Ni catalysts (entry 15).
Scheme 1 Synthesis of pyrazoles

Table 1 Screening Optimal Conditions[a]

Entry	[Ni]	Additive	Isolated yield (%)
1	NiCl$_2$	–	28
2	NiBr$_2$	–	40
3	NiCl$_2$(dppe)$_2$	–	29
4	NiCl$_2$(PCy$_3$)$_2$	–	28
5	(C$_5$H$_5$)Ni(II)Cl(PPh$_3$)	–	59
6	Ni(PPh$_3$)$_4$	–	40
7	(C$_5$H$_5$)Ni(II)Cl(PPh$_3$)	PhCO$_2$H	75
8	(C$_5$H$_5$)Ni(II)Cl(PPh$_3$)	p-MeOC$_6$H$_4$CO$_2$H	51
9	(C$_5$H$_5$)Ni(II)Cl(PPh$_3$)	p-CNC$_6$H$_4$CO$_2$H	64
10	(C$_5$H$_5$)Ni(II)Cl(PPh$_3$)	AcOH	51
11	(C$_5$H$_5$)Ni(II)Cl(PPh$_3$)	PivOH	43
12[b]	(C$_5$H$_5$)Ni(II)Cl(PPh$_3$)	PhCO$_2$H	74
13[c]	(C$_5$H$_5$)Ni(II)Cl(PPh$_3$)	PhCO$_2$H	trace
14[c]	Ni(PPh$_3$)$_4$	PhCO$_2$H	0
15	–	PhCO$_2$H	0

[a] Reaction conditions: **1a** (0.3 mmol), [Ni] (5 mol%), additive (1 equiv) and 1,2-dichloroethane (2 mL) at 80 °C for 12 h under air atmosphere. (C$_5$H$_5$)Ni(II)Cl(PPh$_3$) = [chloro(cyclopentadienyl)(triphenylphosphine)nickel(II)]. Aniline (**3a**) was observed by GC–MS analysis.
[b] The reaction was carried out under O$_2$ atmosphere.
[c] The reaction was carried out under argon atmosphere.

The structure of **2a** was unambiguously confirmed by the single-crystal X-ray diffraction analysis.

As shown in Scheme 2, the above cyclotrimerization protocol was found to be applicable to a diverse range of α-amino arylketones **1** in the presence of (C$_5$H$_5$)Ni(II)Cl(PPh$_3$), PhCO$_2$H and air.[10] Initially, a variety of 2-(substituted arylamino)-1-phenylethanone were investigated under the optimal conditions (products **2b–g**): several substituents, such as Me, MeO, Cl and F, on the aryl ring of the arylamino moiety were tolerated well. Methyl-substituted substrates **1b–d**, for instance, were successfully cyclotrimerized in moderate yields, and the reactive order was found to be *para* > *meta* > *ortho* (products **2b–d**). Importantly, functional groups F and Cl were compatible with the optimal conditions, thereby facilitating additional modifications at the halogenated positions (products **2f**, **2g**, **2j**, **2m**, **2r** and **2s**). It is noteworthy that 2-amino-1-*p*-tolylethanones **1h–k** with an aryl group,

such as Ph, 4-MeOC$_6$H$_4$, 4-ClC$_6$H$_4$ or 2,3-dihydro-1*H*-inden-5-yl group, on the amino moiety successfully underwent the cyclotrimerization in the presence of (C$_5$H$_5$)Ni(II)Cl(PPh$_3$), PhCO$_2$H and air (products **2h–k**).

Scheme 2 (C$_5$H$_5$)Ni(II)Cl(PPh$_3$)-Catalyzed cyclotrimerization of α-amino ketones (**1**) in the presence of PhCOOH. *Reagents and conditions*: **1** (0.3 mmol), (C$_5$H$_5$)Ni(II)Cl(PPh$_3$) (5 mol%), PhCOOH (1 equiv) and DCE (2 mL) at 80 °C for 12 h under air atmosphere. [a] A dimerization/deamination product, (*E*)-2-(phenylamino)-1,4-bis(4-cyanophenyl)but-2-ene-1,4-dione (**4n**), was obtained in 55% yield. [b] A dimerization/deamination product, (*E*)-2-(phenylamino)-1,4-bis[4-(trifluoromethyl)phenyl]but-2-ene-1,4-dione (**4o**), was obtained in 49% yield. [c] A dimerization/deamination product, (*E*)-2-(phenylamino)-1,4-di(thiophen-2-yl)but-2-ene-1,4-dione (**4q**), was obtained in 24% yield.

We next set out to examine the effect of substituents on the aryl group of the 1-arylethanone moiety under the optimal conditions (products **2l–s**). The results disclosed that a number of substituents, including MeO, Cl, CN, and CF$_3$, displayed reactivity for the reaction, but the electron-donating groups were superior to the electron-withdrawing groups (products **2l–o**). Using substrates with the electron-withdrawing groups, however, the selectivity was

shifted toward dimerization as the major reaction. For example, treatment of substrate **1n** with a CN group with $(C_5H_5)Ni(II)Cl(PPh_3)$, $PhCO_2H$ and air provided the corresponding dimerization product **4n** in 55% yield. We are pleased to disclose that naphthalen-1-ylketone (**1p**) underwent the cyclotrimerization smoothly to offer the desired product **2p** in 65% yield. Notably, heterocycle-containing substrate, 2-(phenylamino)-1-(thiophen-2-yl)ethanone (**1q**), was also suitable for the reaction, thereby making this methodology more useful for the preparation of pharmaceuticals and natural products. The reaction of diCl-substituted substrate **1r** also proceeded smoothly, albeit in 30% yield (product **2r**). In the presence of $(C_5H_6)Ni(II)Cl(PPh)$, PhCOOH and air, substrate **1s** with a Me group and a F group in different aryl rings furnished the desired product **2s** in moderate yield. However, ethyl 2-(phenylamino)acetate (**1t**), 2-aminophenylethanone (**1u**) and 1-(phenylamino)propan-2-one (**1v**) resulted in no detectable cyclotrimerization products.

The obtained pyrazole **2a** was employed to synthesize diheterocycle **5a** (equation 1 in Scheme 3). In the presence of KBH_4, (Z)-3-benzylidene-1,2,4,6-tetraphenyl-2,3,4,6-tetrahydro-1H-furo[3,4-c]pyrazole (**5a**) was prepared in 59% yield, which is a structural unit found in some bioactive molecules.[11]

During the reaction of substrate **1a**, imine **6a** as a side-product was observed by in situ GC–MS analysis.[12] Indeed, imine **6a** could be cyclotrimerized leading to product **2a** in the presence of Ni catalyst, such as $(C_5H_5)Ni(II)Cl(PPh_3)$, $Ni(cod)_2$ or $Ni(Ph_3)_4$, albeit with lower activity of the latter two Ni catalysts (equation 2 in Scheme 3), suggesting that this present cyclotrimerization reaction may proceed via the first generation of an imine intermediate **6a**.

Notably, the results in Table 1 also disclosed that without either air or Ni catalysts the cyclotrimerization reaction of substrate **1a** could not take place even in the presence of $PhCO_2H$ (entries 13 and 14 in Table 1). These suggest that Ni complex is the real catalyst, and $PhCO_2H$ is only used to promote the reaction.

Consequently, two possible mechanisms outlined in Scheme 4 are proposed on the basis of the results described above and by the in situ HRMS analysis data (Schemes S1 and S2, and Figures S1 and S2 in Supporting Information).[12] Initially, substrate **1a** may proceed via two pathways, one is directly transferred into intermediate **A** with the aid of the $Ni^{II}/[O]$ system, and the other includes the formation of imine **6a** in the presence of Ni^{II} and air, followed by reaction of imine **6a** with Ni^{II} and [O] to afford the intermediate **A**.[11] Dimerization of the intermediate **A** with a molecule of imine **6a** offers intermediate **B**, followed by a hydride shift which furnishes the intermediate **C**. Intermediate **D** is achieved by insertion of Ni into the C–N bond in intermediate **C**. The third molecule of imine **6a** is used to react with intermediate **D** with the aid of acid,[13] providing intermediate **E**. Isomerization of intermediate **E** affords intermediate **F**. Finally, reductive elimination and dehydroxylation reaction of intermediate **F** produces the desired product **2a**.[9] To rule out a radical process for the current reaction, a control experiment using a radical scavenger (TEMPO) was carried out: a stoi-
Scheme 3
Scheme 4 Possible mechanism

chiometric amount of TEMPO (1 equiv) had no effect on the reaction.

In summary, we have described a new route to polysubstituted 3-methylene-2,3-dihydro-1*H*-pyrazoles via Ni-catalyzed oxidative cyclotrimerization of α-amino carbonyl compounds, which utilizes three highly reactive functional groups, the active α-C–H bond, the free N–H bond and the carbonyl group, in α-amino carbonyl compounds to construct three new chemical bonds: two C–C bonds and one N–N bond. Importantly, this method employs accessible α-amino carbonyl compounds as the starting materials, which facilitates introduction of the α-amino carbonyl units into pyrazoles and makes the obtained pyrazole compounds more useful with some special complex bioactivities. Applications of this new Ni-catalyzed transformation in organic synthesis are currently underway in our laboratory.

(10) **Typical Experimental Procedure for the Ni-Catalyzed Cyclotrimerization of α-Amino Arylketones**: To a

Schlenk tube were added α-amino arylketones **1** (0.3 mmol), (C₅H₅)Ni(II)Cl(PPh₃) (5 mol%), PhCOOH (1 equiv) and DCE (CH₂ClCH₂Cl, 2 mL). Then the tube was sealed under air and stirred at 80 °C (the temperature of the heating bath) for the indicated time until complete consumption of the starting material as monitored by TLC and GC–MS analysis. After the reaction was finished, the reaction mixture was diluted with Et₂O, filtered by a short crude silica gel column and concentrated in vacuum, and the resulting residue was purified by silica gel column chromatography (hexane–EtOAc) to afford the desired product **2**.

(Z)-(5-Benzylidene-1,2-diphenyl-2,5-dihydro-1*H*-pyrazole-3,4-diyl)bis(phenylmethanone) (2a): Yellow solid: 38.9 mg, 75% yield; mp 190.2–191.5 °C (uncorrected). ¹H NMR (500 MHz, CDCl₃): δ = 8.11 (d, *J* = 7.4 Hz, 1 H), 7.47 (t, *J* = 7.7 Hz, 1 H), 7.21–7.32 (m, 13 H), 7.09 (td, *J* = 7.3, 4.0 Hz, 7 H), 6.92–6.95 (m, 2 H), 6.59–6.62 (d, *J* = 8.5 Hz, 2 H). ¹³C NMR (125 MHz, CDCl₃): δ = 191.9, 186.3, 144.0, 139.1, 138.7, 136.8, 132.6, 132.5, 131.4, 131.2, 130.9, 129.2, 128.7, 128.1, 127.9, 127.7, 127.5, 127.4, 127.0, 126.9, 126.8, 126.6, 125.3, 122.8, 120.0, 114.2. IR (neat): 1715, 1593, 1448, 1363, 1223, 958, 804, 736, 690 cm⁻¹. LRMS (EI, 70 eV): *m/z* (%) = 518 [M⁺] (100), 295 (94). HRMS (ESI): *m/z* [M + H]⁺ calcd for C₃₆H₂₆N₂O₂: 519.2067; found: 519.2089.
