

Highly Enantioselective Addition of Allyltrimethylsilane to Aldehydes

Selected examples:

Significance: List and co-workers report the first general, highly enantioselective, organocatalytic addition of allyltrimethylsilane to aldehydes (the Hosomi–Sakurai reaction). This transformation is enabled by newly developed highly confined imido-diphosphorimidates **IDPi**. Various aromatic and aliphatic aldehydes are tolerated under the reaction conditions, affording the desired products in good to excellent yields and enantioselectivities (er \leq 98:2).

Comment: The **IDPi** motif, which can be accessed by a single-flask synthesis from 3,3'-disubstituted BINOL derivatives, is a combination of the recently developed highly confined imido-diphosphates (*Nature* **2012**, *483*, 315) and highly acidic BINOL-derived phosphoramididates (*Synlett* **2016**, *27*, 156).
