Abstract The selectivity of the substitution reaction of phosphoryl chloride with organometallic reagents was investigated using NMR spectroscopy. This led to the discovery that the selectivity of the substitution reaction can be tuned by choosing a proper organometallic reagent. A phosphinate could be obtained by using a Grignard reagent whereas an organozinc reagent provided a phosphonate. Based on these results, one-pot synthetic methods for the preparation of phosphinates and phosphonates using commercially available starting materials were developed. Both methods allow the synthesis of a broad range of either phosphinate or phosphonate derivatives in a straightforward and general procedure. Moreover, using these one-pot procedures, mixed systems substituted with different alkyl/aryl groups can be prepared.

Key words selectivity, substitution, phosphoryl chloride, phosphinate, phosphonate, Grignard reagent, organozinc reagent

Organophosphinates 1 and organophosphonates 2, the ester derivatives of organophosphinic 3 and organophosphonic acids, can be seen as intermediate compounds between the corresponding phosphates and phosphine oxides. Hence, the chemical, physical, and biological properties of phosphinates 1 and phosphonates 2 are in between these two extremes. The synthesis of phosphinate 1 and phosphonate 2 derivatives is therefore an attractive approach to fine-tune the characteristics of organophosphorus(V) compounds. The attractiveness of these two classes of molecules is illustrated by their many applications. For example, they are used as halogen-free flame retardants in plastics, as extractants for liquid–liquid extraction in hydro-metallurgy, and solvometallurgy, as grafting agents to modify metal oxide surfaces, and as reagents for olefination reactions. Moreover, phosphinates 1 and phosphonates 2 are important in the treatment of several diseases, typically as prodrugs for their corresponding acid derivatives. Noteworthy examples are nucleoside phosphonates applied in the treatment of various DNA virus and retrovirus infections, such as hepatitis B and HIV.

However, the utility of organophosphinates 1 is limited by their tedious multistep synthesis. The corresponding phosphinic acids 3 are the key intermediates in this synthesis and they form, after activation to phosphinic halides, the desired phosphinates 1 via a nucleophilic substitution reaction (Scheme 1, path A). Of course, first the organophosphinic acids 3 need to be prepared using, for example, a hydrophosphonation reaction of alkenes with hypophosphorous acid 4; a reaction between dialkyl hydrogen phosphites 5 and organometallic reagents followed by oxidation, etc. A generic strategy towards phosphinates 1 is not available yet. The used synthetic pathway is therefore dependent on the structure of the desired phosphinate 1.

A more generic strategy is known for organophosphonates 2. Phosphorus trichloride (6) can be substituted with an excess of alcohol in the presence of base and the resulting phosphate ester 7 can be subjected to an Michaelis–Arbuzov reaction with a haloalkane to form a phosphonate 2 (Scheme 1, path B). However, the latter reaction requires high temperatures and only primary haloalkanes react readily. Under certain conditions, secondary haloalkanes might also react, but tertiary haloalkanes and haloarenes are unreactive in the Michaelis–Arbuzov reaction. Moreover, when the alkyl group of the alcohol and the haloalkane are different, a mixture of phosphonates 2 might be formed. Besides this strategy, other less general synthetic pathways towards phosphonates 2 have also been described.

A more straightforward and general strategy to synthesize both phosphinates 1 and phosphonates 2 could be envisioned as the reaction between phosphoryl chloride (8)
and, respectively, two or one equivalents of Grignard reagent, followed by quenching with an excess of alcohol (Scheme 1, path C). This one-pot procedure would be shorter than the conventional synthetic strategies, would use milder reaction conditions (i.e., heating is not required) and would allow different substituents on the phosphorus ($R^1$) and oxygen ($R^2$) atoms. However, this one-pot protocol is currently not used for the synthesis of either phosphinates 1 or phosphonates 2. A poorly selective substitution of phosphoryl chloride ($R^2$) with Grignard reagents is often cited as the reason why this one-pot procedure is unsuitable for the synthesis of phosphinates 1 and phosphonates 2. According to the literature, Grignard reagents have a tendency to completely substitute phosphoryl chloride ($R^2$), but a detailed study of the extent of the side reactions has not been reported yet. It should also be noted that many examples that resulted in over-substitution used an unfavorable addition order of the reagents, namely phosphoryl chloride ($R^2$) was added to the Grignard reagent. Adding the Grignard reagent to phosphoryl chloride ($R^2$) can be expected to give better yields. Moreover, reported examples of the reaction between phosphoryl chloride ($R^2$) and organometallic reagents were typically limited to aryl Grignard reagents, whereas alkyl groups and other organometallic reagents have been much less studied. Furthermore, most of these reports involved quenching the reaction with water, forming a phosphinic or phosphonic acid. Preparing esters by quenching the reaction with different alcohols is less common.

Given the current poor understanding of the extent of the selectivity for the substitution reaction of phosphoryl chloride ($R^2$) with organometallic reagents, we set out to investigate this selectivity using NMR spectroscopy and to examine the possibility of using this substitution reaction in the synthesis of phosphinates 1 and phosphonates 2. Based on the results, practical one-pot syntheses of phosphinates 1 and phosphonates 2 using commercially available starting materials were developed (Scheme 1, path C).

The first step of this work was to study the selectivity of the substitution reaction of phosphoryl chloride ($R^2$) with one or two equivalents of Grignard reagent. In order to limit over-substitution, the Grignard reagent was slowly added to an anhydrous diethyl ether solution of phosphoryl chloride ($R^2$) while the solution was being cooled using an icesalt mixture. Diethyl ether was chosen as the reaction solvent because all the Grignard reagents used in this study are commercially available as diethyl ether solutions. After addition of the Grignard reagent, the reaction was stirred at room temperature to achieve complete conversion. Samples were then taken and analyzed by $^{31}$P NMR spectroscopy to estimate the relative amounts of the formed products. Preliminary experiments with phenylmagnesium bromide showed that the formed phenylphosphonic dichloride and diphenylphosphinic chloride were too poorly soluble in diethyl ether to allow analysis of the reaction mixture by $^{31}$P NMR spectroscopy. Because octylphosphonic dichloride and dioctylphosphinic chloride are more soluble, the selectivity of the substitution reaction was determined by using octylmagnesium bromide as the Grignard reagent.

Reacting one equivalent of octylmagnesium bromide with phosphoryl chloride ($R^2$) resulted in less than 10% of the desired octylphosphonic dichloride compound 9a (Table 1, entry 1). Instead, about half of the reaction mixture was doubly reacted dioctylphosphinic chloride (10a) and the other half unreacted phosphoryl chloride ($R^2$). Thus, the added octylmagnesium bromide reacted twice with phosphoryl chloride ($R^2$), which is in agreement with the reported tendency of Grignard reagents to completely substitute phosphoryl chloride ($R^2$). This lack of selectivity for monofunctionalization might be explained by considering the magnesium salt that is formed as a side product during the reaction. This Lewis acid will probably coordinate stronger to the more electron-rich octylphosphonic dichloride (9a) than to phosphoryl chloride ($R^2$), making the resulting octylphosphonic dichloride complex more electrophilic and hence more reactive toward the Grignard reagent.

In contrast to using one equivalent, reacting two equivalents of octylmagnesium bromide with phosphoryl chloride ($R^2$) did result in a selective reaction (Table 1, entry 4). Almost 75% of the reaction mixture consisted of the desired dioctylphosphinic chloride (10a), whereas only approximately 15% octylphosphonic dichloride (9a) and a trace of trioctylphosphine oxide were formed. This shows that, contrary to what is typically assumed in the literature, selective disubstitution of phosphoryl chloride ($R^2$) with two equivalents of a Grignard reagent is possible. This selectivity might be explained by considering the steric hindrance of...
the reaction between dioctylphosphinic chloride (10a) and the Grignard reagent. Hence, this side reaction with dioc-
tyolphosphinic chloride (10a) will be less favorable than the
less sterically hindered reaction with octylphosphonic di-
chloride (9a).

Given that the above-mentioned reaction mixture con-
stituted mostly of dioctylphosphinic chloride, it should be
possible to synthesize octyl dioctylphosphinate (1a) by
quenching the reaction with an excess of 1-octanol. After
addition of 1-octanol at a temperature below 0 °C, the reac-
tion was stirred at room temperature. After addition of
one equivalents of octylmagnesium bromide with anhydrous CdCl2 in dieth-
ylether at room temperature. After addition of one equiva-
HCl could be neutralized and complete conver-
sion could be achieved. This resulted in a reaction mixture
that consisted mostly of the desired octyl dioctylphosphi-
nate (1a) together with a small amount of dioctyl octyl-
phosphonate (2a). After extractive workup and purifi-
cation by column chromatography, octyl dioctylphosphinate (1a)
was isolated in a good yield of 63% (Scheme 2).

\[ \text{Scheme 2 One-pot synthesis of phosphinates 1 using a selective substitution of P(OC)Cl2 with 2 equiv of Grignard reagents} \]

Similar results could be obtained with other alkyl
groups (Scheme 2). Reaction of phosphoryl chloride (8)
with two equivalents of dodecylmagnesium bromide, fol-
lowed by quenching with an excess of 1-dodecanol provi-
ed dodecyl didodeclyphosphinate (1b) in an isolated yield of
55%. Furthermore, the more sterically hindered 2-ethyl-
hexyl bis(2-ethylhexyl)phosphinate (1c) could be synthe-
sized in a similar yield by starting from the correspondingly
 branched Grignard reagent and alcohol. Besides alkyl
Grignard reagents, phenylmagnesium bromide also allowed
selective disubstitution of phosphoryl chloride (8). Howev-
ner, phenol was not reactive enough to substitute the result-
ing diphenylphosphinic chloride intermediate. Nonetheless,
1-octanol could react with diphenylphosphinic chloride and
carbonyl diphenylphosphinate (1d) was isolated in a slight-
ly lower yield than the other synthesized phosphinates 1.

The last example illustrates another advantage of this
one-pot procedure, namely that the substituents on the
phosphorus (R) and oxygen (R') atoms of the resulting
phosphinate 1 do not need to be the same. Mixed phosphi-
nates 1d-f can be easily made using the same procedure
and in similar yields. For example, reaction of phosphoryl
chloride (8) with two equivalents of octylmagnesium bro-
mide followed by quenching with an excess of 2-ethylhexa-
non resulted in 2-ethylhexyl dioctylphosphinate (1e) in a
good yield of 58%. In a similar way, a phosphinic acid could
be synthesized if the dioctylphosphinic chloride intermedi-
ate was quenched with water. After extraction and recrys-
tallization, dioctylphosphinic acid (1f) was isolated in an
acceptable yield.

This one-pot procedure is, compared to the different
traditional multistep synthesis routes of phosphinates 1,
much more straightforward and general. Moreover, the
overall yield of this process is, due to its shorter synthetic
pathway, as good as or even better than those obtained via
the traditional synthesis routes (Scheme 1, path A).9,10,11,13

Given the success of disubstitution of phosphoryl
chloride (8), selective monofunctionalization was further
investigated using organometallic reagents other than
Grignard reagents. Similar to phosphoryl chloride (8), reac-
tion of phosphorus trichloride (6) with Grignard reagents
is known to result in over-substitution.14,17 However, it has
been reported that reaction of phosphorus trichloride (6)
with milder alkylating reagents, such as organomercury,18
organolead19 and organocadmium20 reagents, did allow
selective monoalkylation. Therefore, it was tested whether
an organocadmium reagent could result in a similar selec-
tive monofunctionalization reaction with phosphoryl chlo-
ride (8). Organomercury and organolead compounds were
not investigated due to their very high toxicity.21 It should
be mentioned that also organocadmium compounds are
toxic; however, they are less toxic than organomercury
compounds and they are more commonly used as reagents
in organic synthesis than organolead compounds.22

Diocetyl cadmium was synthesized in situ by the reaction
of octylmagnesium bromide with anhydrous CdCl2, in dieth-
yl ether at room temperature. After addition of one equiva-
lent (relative to the initial amount of octylmagnesium bro-
mide) of phosphoryl chloride (8) at a temperature below
0 °C, the reaction mixture was stirred at room temperature.
Unfortunately, no reaction was observed at this tempera-
ture. Nevertheless, a slow reaction did occur when the reac-

* R = n-C8H17.
* Percentage of phosphorus compounds in the reaction mixture as estima-
ted by 31P NMR analysis.
* Compound was not detected.
tion mixture was heated at reflux. Over-substitution to dioctylphosphonic chloride (10a) was not detected and the major product was the desired octylphosphonic dichloride (9a) (Table 1, entry 2). Hence, with this less strongly alkylating organocadmium reagent, selective monofunctionalization of phosphoryl chloride (8) was indeed possible. After 45 hours, almost half of the reaction mixture consisted of the monoalkylated product, the rest was mostly unreacted phosphoryl chloride (8).

As diocetylcadmium was not reactive enough to allow complete conversion, even after 45 hours of reflux, diocetylzinc was used as a more reactive and less toxic alternative. Diocetylzinc was synthesized and used in a similar manner as diocetylcadmium. However, due to its higher reactivity, diocetylzinc did react with phosphoryl chloride (8) at room temperature. After 20 hours, almost 75% of the reaction mixture consisted of the desired octylphosphonic dichloride (9a) (Table 1, entry 3). Diocetylzinc reacted, just like diocetylcadmium, selectively with phosphoryl chloride (8) and over-substitution to dioctylphosphinic chloride (10a) was not detected. The amount of monoalkyl product in the reaction mixture after reaction with 0.5 equivalent of diocetylzinc (Table 1, entry 3) was similar to the amount of dioctyl product after reaction with 2 equivalents of Grignard reagent (Table 1, entry 4). Therefore, it is possible to tune the selectivity of the substitution reaction of phosphoryl chloride (8) by choosing a proper organometallic reagent.

Selective monoalkylation of phosphoryl chloride (8) to octylphosphonic dichloride was used next to develop a one-pot procedure for the synthesis of the corresponding phosphonate 2a. Hence, the reaction of diocetylzinc with phosphoryl chloride (8) was quenched with an excess of 1-octanol in the presence of pyridine. The reaction mixture was cooled below 0 °C during the addition of these two reagents and was afterwards stirred at room temperature until 31P NMR analysis showed complete consumption of the octylphosphonic dichloride intermediate. The resulting mixture consisted mostly of dioctyl octylphosphonate (2a) together with a smaller amount of triocetyl phosphate. This triocetyl phosphate was formed from the reaction between 1-octanol and the remaining phosphoryl chloride (8). Unfortunately, the desired diocetyl octylphosphonate (2a) was found to be less stable than the corresponding phosphinate 1a. Therefore, more product was lost during purification and dioctyl octylphosphonate (2a) was isolated in a lower yield of 46% (Scheme 3).

The scope of the one-pot synthesis of phosphonates 2 (Scheme 3) is the same as the scope of the one-pot synthesis of phosphinates 1 (Scheme 2). Unfortunately, all synthesized phosphonates 2 were less stable than their phosphinate analogues 1 and were isolated in a lower yield. Nonetheless, phosphonates 2 with other alkyl groups, such as dodecyl (in compound 2b) and the branched 2-ethylhexyl (in compounds 2c and 2e) could be synthesized in moderate yields. In contrast, reaction of phosphoryl chloride (8) with diphenylzinc followed by quenching with an excess of 1-octanol gave the corresponding dioctyl phenylphosphonate (2d) in a low yield. The major product was actually triocetyl phosphate and a significant amount of octyl diphenylphosphinate (1d) was also present, indicating that 0.5 equivalent of diphenylzinc did not react selectively with phosphoryl chloride (8).

Mixed phosphonates, with different substituents on the phosphorus (R1) and oxygen (R2) atoms, can be easily prepared using this one-pot procedure. For example, bis(2-ethylhexyl) octylphosphonate (2e) was obtained in a similar yield as its triocetyl derivative 2a by reacting diocetylzinc with phosphoryl chloride (8) followed by quenching with an excess of 2-ethylhexanol. Moreover, octylphosphonic acid (2f) can be synthesized by quenching the reaction of dioctylzinc with water. Anhydride formation limited the yield of the desired acid 2f but this can be reduced by not adding pyridine to the reaction mixture. In this way, octylphosphonic acid (2f) was isolated in a moderate yield.

The yields of the one-pot synthesis of phosphonates 2 are in general lower than those obtained for the traditional synthesis of phosphonates 2 based on the Michaelis–Arbuzov reaction (Scheme 1, path B).11,12,13 Nevertheless, this new procedure is a viable alternative for those cases where the Michaelis–Arbuzov reaction does not work.13 Moreover, this one-pot synthesis requires only one purification step, compared to the two purification steps required in the traditional strategy, uses milder reaction conditions than the Michaelis–Arbuzov reaction and is well suited for the synthesis of mixed phosphonates.

In conclusion, the selectivity of the substitution reaction of phosphoryl chloride (8) with organometallic reagents was investigated using NMR spectroscopy. It was found that 2 equivalents of octylmagnesium bromide reacted selectively to dioctylphosphinic chloride and that 0.5 equivalent of diocetylzinc reacted selectively to octylphosphonic dichloride. Hence, it is possible to tune the selectivity of the substitution reaction of phosphoryl chloride (8) by choosing a proper organometallic reagent. These results were used to develop one-pot synthetic methods for the preparation of phosphinates 1 and phosphonates 2 using commercially available Grignard reagents and alcohols. In this way,
Phosphinates 1 were synthesized in good yields and phosphonates 2, due to their lower stability, in moderate yields. Both procedures allow the synthesis of compounds with different substituents, of mixed systems and of their phosphinic and phosphonic acid derivatives. Compared to the traditional strategies to synthesize phosphinates 1 and phosphonates 2, these one-pot procedures are shorter, more straightforward and more general.

All reactions were carried out in oven-dried glassware under a N2 atmosphere. POCl3 (99%), octylmagnesium bromide (2.0 M in Et2O), (2-ethylhexyl)magnesium bromide (1.0 M in Et2O), anhyd CdCl2 (99%), 1-octanol (99%), and 1-dodecanol (98%) were purchased from Acros Organics. Dodecymagnesium bromide (1.0 M in Et2O) and phenylmagnesium bromide (1.0 M in Et2O), were purchased from VWR and anhyd ZnCl2 (98–100%) was obtained using a MBRAUN SPS-800 system. For column chromatography, 0.060–0.200 mm (60 A) silica gel from Acros Organics was used as the stationary phase. All chemicals were used as received without further purification.

1H and 13C NMR spectra were recorded at r.t. in CDC13 on a Bruker Ascend 400 MHz instrument operating at a frequency of 400 MHz for 1H, 100 MHz for 13C and 162 MHz for 31P. 1H chemical shifts were referenced to TMS (0.00 ppm). 13C chemical shifts were referenced to the CDC13 solvent signal (77.16 ppm) and 31P chemical shifts were referenced to aq 85% H3PO4 (0.00 ppm). Melting points were determined on a Mettler-Toledo DSC882e instrument under a He atmosphere using a heating rate of 5 °C min–1. IR spectra were recorded on a Bruker Vertex 70 ATR-FTIR spectrophotometer. Low-resolution mass spectra were recorded on a Thermo Finnigan LCQ Advantage instrument (ESI mode). CHN elemental analysis was performed on a Thermo Scientific Flash 2000 Organic Elemental Analyzer.

**Phosphinates 1; General Procedure**
To an oven-dried 100 mL two-necked flask, fitted with a reflux condenser were added anhyd Et2O (amount depending on the concentration of the used Grignard reagent solution) and POCl3 (0.93 ml, 10 mmol, 1 equiv). The solution was cooled in an ice-salt mixture and a Grignard reagent (20 mmol, 2 equiv) solution in Et2O was slowly added. After stirring with cooling for 30 min, the reaction mixture was brought to r.t. and stirred for the indicated time. The mixture was then cooled again in an ice-salt mixture and the alcohol (20 mmol, 2 equiv) and pyridine (1.8 ml, 22 mmol, 2.2 equiv) were slowly added. Stirring with cooling for 5 min was followed by reaction at r.t. The reaction was quenched after the indicated time by cooling in an ice-salt mixture and adding sat. aq NH4Cl (5 ml). The crude mixture was then poured into CH2Cl2 (100 mL), washed three times with dil HCl (1–2%, 100 mL in total), dried (MgSO4), filtered, and evaporated to dryness. The excess of alcohol was removed using a short-path vacuum distillation apparatus and the resulting crude product was purified by column chromatography.

**Octyl Diocetylphosphinate (1a)**
[CAS Reg. No. 7065-29-4]
Prepared according to the general phosphinate synthesis procedure using anhyd Et2O (20 ml), octylmagnesium bromide (10 ml, 20 mmol, 2 equiv), and 1-octanol (3.2 ml, 20 mmol, 2 equiv). The reaction with the Grignard reagent was stirred at r.t. for 5 h and the reaction with the alcohol was stirred at r.t. for 21 h. After extractive work-up, the excess of 1-octanol was removed using a short-path vacuum distillation apparatus at 250 °C. The resulting crude product was purified by column chromatography (silica gel; CH2Cl2/EtOAoc; 8:2 v/v), providing the pure compound as a slightly yellowish liquid; yield: 2.52 g (63%).

31P NMR (CDCl3, 162 MHz): δ = 57.8.

**Dodecyl Didodecylphosphinate (1b)**
Prepared according to the general phosphinate synthesis procedure using anhyd Et2O (10 ml), dodecylmagnesium bromide (20 ml, 20 mmol, 2 equiv), and 1-dodecanol (4.5 ml, 20 mmol, 2 equiv). The reaction with the Grignard reagent was stirred at r.t. for 24 h and the reaction with the alcohol was stirred at r.t. for 24 h. After extractive work-up, the excess of 1-dodecanol was removed using a short-path vacuum distillation apparatus at 300 °C. The resulting crude product was purified by column chromatography (silica gel; CH2Cl2/EtOAoc; 9:1 v/v), providing the pure compound as a white solid; yield: 3.16 g (55%); mp 39–41 °C.

IR (ATR): 2916, 2848, 1463, 1184, 966, 773 cm–1.

1H NMR (CDCl3, 400 MHz): δ = 3.95 (q, J = 6.6 Hz, 2 H), 1.75–1.61 (m, 6 H), 1.61–1.50 (m, 4 H), 1.40–1.22 (m, 54 H), 0.88 (t, J = 6.6 Hz, 9 H).

31P NMR (CDCl3, 162 MHz): δ = 57.8.

**2-Ethylhexyl Bis(2-ethylhexyl)phosphinate (1c)**
[CAS Reg. No. 36333-32-1]
Prepared according to the general phosphinate synthesis procedure using anhyd Et2O (10 ml), (2-ethylhexyl)magnesium bromide (20 ml, 20 mmol, 2 equiv), and 2-ethyl-1-hexanol (3.1 ml, 20 mmol, 2 equiv). The reaction with the Grignard reagent was stirred at r.t. for 18.5 h and the reaction with the alcohol was stirred at r.t. for 3 days. After extractive work-up, the excess of 2-ethyl-1-hexanol was removed using a short-path vacuum distillation apparatus at 150 °C. The resulting crude product was purified by column chromatography (silica gel; CH2Cl2/EtOAoc; 95:5 v/v), providing the pure compound as a colorless liquid; yield: 2.08 g (52%).

IR (ATR): 2957, 2927, 1460, 1224, 1017, 820 cm–1.

1H NMR (CDCl3, 400 MHz): δ = 3.92–3.79 (m, 2 H), 1.81–1.71 (m, 2 H), 1.66–1.60 (m, 4 H), 1.58–1.34 (m, 11 H), 1.34–1.16 (m, 14 H), 1.07–0.69 (m, 18 H).
[CAS Reg. No. 3389-73-9]

Prepared according to the general phosphinate synthesis procedure using anhyd Et₂O (40 mL), phenylmagnesium bromide (6.7 mL, 20 mmol, 2 equiv), and 1-octanol (3.2 mL, 20 mmol, 2 equiv). The reaction with the Grignard reagent was stirred at r.t. for 21.5 h and the reaction with the alcohol was stirred at r.t. for 25.5 h. After extractive workup, the excess of 1-octanol was removed using a short-path vacuum distillation apparatus at 250 °C. The resulting crude product was purified by column chromatography (silica gel; CH₂Cl₂/EtOAc; 8:2 v/v), providing the pure compound as a slightly yellowish liquid; yield: 1.45 g (44%).

IR (ATR): 2915, 2846, 1463, 967, 779 cm⁻¹.
1H NMR (CDCl₃, 400 MHz): δ = 7.81 (dd, J = 12.2, 8.2, 1.3 Hz, 4 H), 7.56–7.48 (m, 2 H), 7.49–7.40 (m, 4 H), 4.02 (q, J = 6.6 Hz, 2 H), 1.76–1.68 (m, 2 H), 1.43–1.34 (m, 2 H), 1.33–1.22 (m, 8 H), 0.87 (t, J = 6.9 Hz, 3 H).
13C NMR (CDCl₃, 100 MHz): δ = 132.6, 132.2, 132.2, 131.9, 131.8, 131.2, 128.7, 128.6, 65.2, 65.2, 31.9, 30.7, 30.7, 29.3, 29.3, 25.8, 22.8, 14.2.
31P NMR (CDCl₃, 162 MHz): δ = 31.3.

2-Ethylhexyl Dioctylphosphinate (1e)
[CAS Reg. No. 140069-65-6]

Prepared according to the general phosphinate synthesis procedure using anhyd Et₂O (20 mL), octylmagnesium bromide (10 mL, 20 mmol, 2 equiv), and 2-ethyl-1-hexanol (3.1 mL, 20 mmol, 2 equiv). The reaction with the Grignard reagent was stirred at r.t. for 24 h. After extractive workup, the excess of 2-ethyl-1-hexanol was removed using a short-path vacuum distillation apparatus at 150 °C. The resulting crude product was purified by column chromatography (silica gel; CH₂Cl₂/EtOAc; 8:2 v/v), providing the pure compound as a slightly yellowish liquid; yield: 2.35 g (58%).

IR (ATR): 2924, 2855, 1461, 1208, 1016, 811 cm⁻¹.
1H NMR (CDCl₃, 400 MHz): δ = 3.90–3.81 (m, 2 H), 1.75–1.62 (m, 4 H), 1.61–1.50 (m, 5 H), 1.42–1.34 (m, 6 H), 1.33–1.22 (m, 22 H), 0.96–0.83 (m, 12 H).
31P NMR (CDCl₃, 162 MHz): δ = 57.6.

Dioctylphosphinic Acid (1f)
[CAS Reg. No. 683-19-2]

To an oven-dried 100 mL two-neck flask, fitted with a reflux condenser were added anhyd Et₂O (20 mL) and POCl₃ (0.93 mL, 10 mmol, 1 equiv). The solution was cooled in an ice-salt mixture and octylmagnesium bromide (10 mL, 20 mmol, 2 equiv) was slowly added. After stirring with cooling for 30 min, the reaction mixture was brought to r.t. and stirred for 19.5 h. The mixture was then cooled again in an ice-salt mixture, and H₂O (5 mL) and pyridine (1.8 mL, 22 mmol, 2 equiv) were slowly added. Stirring with cooling for 5 min was followed by reaction at r.t. for 7 h. The crude mixture was then poured into CH₂Cl₂ (100 mL), washed three times with dil HCl (1–2%, 100 mL in total), dried (MgSO₄), filtered, and evaporated to dryness. The resulting crude product was purified by recrystallization from hot heptane (50 mL), filtered, and washed with pentane, providing the pure compound as a white solid; yield: 1.52 g (52%); mp 83–84 °C.

IR (ATR): 2915, 2846, 1461, 779 cm⁻¹.
1H NMR (CDCl₃, 400 MHz): δ = 10.52 (s, 1 H), 1.71–1.52 (m, 8 H), 1.43–1.33 (m, 4 H), 1.33–1.20 (m, 16 H), 0.87 (t, J = 6.8 Hz, 6 H).
13C NMR (CDCl₃, 100 MHz): δ = 32.0, 31.1, 31.0, 29.6, 29.3, 29.3, 28.7, 22.8, 21.7, 21.7, 14.2.
31P NMR (CDCl₃, 162 MHz): δ = 60.4.

Phosphonates 2; General Procedure
To an oven-dried 100 mL two-neck flask, fitted with a reflux condenser were added anhyd ZnCl₂ (0.75 g, 5.5 mmol, 0.55 equiv) and anhyd Et₂O (amount depending on the concentration of the used Grignard reagent solution). The mixture was cooled in an ice-bath and a Grignard reagent (10 mmol, 1 equiv) solution in Et₂O was slowly added. The reaction mixture was stirred 10 more min at 0 °C followed by stirring at r.t. for the indicated time. The solution was then cooled in an ice-salt mixture and POCl₃ (0.93 mL, 10 mmol, 1 equiv) was added. After stirring with cooling for 5 min, the mixture was brought to r.t. and stirred for the indicated time. The mixture was cooled again in an ice-salt mixture and the alcohol (30 mmol, 3 equiv) and pyridine (2.7 mL, 33 mmol, 3 equiv) were slowly added. Stirring with cooling for 5 min was followed by reaction at r.t. The reaction was quenched after the indicated time by cooling in an ice-salt mixture and adding dil HCl (1–2%, 5 mL). The crude mixture was then poured into CH₂Cl₂ (100 mL), washed three times with dil HCl (1–2%, 100 mL in total), dried (MgSO₄), filtered, and evaporated to dryness. The excess of alcohol was removed using a short-path vacuum distillation apparatus and the resulting crude product was purified by column chromatography.

Dioctyl Octyolphosphonate (2a)
[CAS Reg. No. 7098-33-1]

Prepared according to the general phosphinate synthesis procedure using anhyd Et₂O (20 mL), octylmagnesium bromide (5 mL, 10 mmol, 1 equiv), and 1-octanol (4.7 mL, 30 mmol, 3 equiv). The corresponding organozinc reagent was synthesized by stirring 2 h at r.t. The reaction with the formed organozinc reagent was stirred at r.t. for 51 h and the reaction with the alcohol was stirred at r.t. for 17 h. After ex-
tractive workup, the excess of 1-octanol was removed using a short-path vacuum distillation apparatus at 200 °C. The resulting crude product was purified by column chromatography (silica gel; CH₂Cl₂/EtOAc; 95:5 v/v), providing the pure compound as a slightly yellowish liquid; yield: 1.92 g (46%).

IR (ATR): 2958, 2928, 1461, 1246, 1011, 869 cm⁻¹.

1H NMR (CDCl₃, 400 MHz): δ = 4.06–3.94 (m, 4 H), 1.77–1.53 (m, 10 H), 1.39–1.25 (m, 28 H), 0.88 (t, J = 6.4 Hz, 9 H).

13C NMR (CDCl₃, 100 MHz): δ = 65.7, 65.6, 32.0, 31.9, 30.9, 30.8, 30.7, 30.7, 29.4, 29.3, 29.2, 26.4, 25.7, 25.0, 22.8, 22.6, 22.6, 14.2.

31P NMR (CDCl₃, 162 MHz): δ = 32.8.

Anal. Calcd for C₃₆H₇₅O₃P: C, 73.67; H, 12.88. Found: C, 74.30; H, 12.22.

**Diocetyl Dodecylphosphonate (2b)**

Prepared according to the general phosphonate synthesis procedure using anhyd Et₂O (15 mL), dodecylmagnesium bromide (10 mL, 10 mmol, 1 equiv), and 1-dodecanol (6.7 mL, 30 mmol, 3 equiv). The corresponding organozinc reagent was synthesized by stirring 3 h at r.t. The reaction with the formed organozinc reagent was stirred at r.t. for 24 h and the reaction with the alcohol was stirred at r.t. for 25 h. After extractive workup, the excess of 1-octanol was removed using a short-path vacuum distillation apparatus at 150 °C. The resulting crude product was purified by column chromatography (silica gel; CH₂Cl₂/EtOAc; 95:5 v/v), providing the pure compound as a white solid; yield: 2.12 g (36%); mp 34–36 °C.

Anal. Calcd for C₃₂H₆₆O₃P: C, 73.67; H, 12.88. Found: C, 74.30; H, 12.82.

**Bis(2-ethylhexyl) Octylphosphonate (2e)**

Prepared according to the general phosphonate synthesis procedure using anhyd Et₂O (20 mL), octylmagnesium bromide (5 mL, 10 mmol, 1 equiv), and 2-ethyl-1-hexanol (4.7 mL, 30 mmol, 3 equiv). The corresponding organozinc reagent was synthesized by stirring 2 h at r.t. The reaction with the formed organozinc reagent was stirred at r.t. for 24 h and the reaction with the alcohol was stirred at r.t. for 25 h. After extractive workup, the excess of 2-ethyl-1-hexanol was removed using a short-path vacuum distillation apparatus at 150 °C. The resulting crude product was purified by column chromatography (silica gel; CH₂Cl₂/EtOAc; 8:2 v/v), providing the pure compound as a slightly yellowish liquid; yield: 1.82 g (43%).

IR (ATR): 2926, 2858, 1461, 1246, 1011, 869 cm⁻¹.

1H NMR (CDCl₃, 400 MHz): δ = 3.98–3.84 (m, 4 H), 1.77–1.67 (m, 2 H), 1.63–1.50 (m, 4 H), 1.45–1.34 (m, 6 H), 1.33–1.20 (m, 20 H), 0.97–0.82 (m, 15 H).

13C NMR (CDCl₃, 100 MHz): δ = 67.7, 67.6, 40.4, 40.4, 32.0, 30.8, 30.7, 30.1, 29.2, 29.2, 29.1, 26.2, 24.8, 23.5, 23.5, 23.1, 22.8, 22.7, 22.6, 14.2, 14.2, 11.1.

31P NMR (CDCl₃, 162 MHz): δ = 32.7.
Octylphosphonic acid (2f)

CAS Reg. No. 4724-48-5

To an oven-dried 100 mL two-neck flask, fitted with a reflux condenser were added anhyd ZnCl₂ (0.75 g, 5.5 mmol, 0.65 equiv) and anhyd Et₂O (20 mL). The mixture was cooled in an ice-bath and octylmagnesium bromide (4.2 mL, 8.4 mmol, 1 equiv) was slowly added. The reaction mixture was stirred 10 more min at 0 °C followed by 2 h at r.t. The solution was then cooled in an ice-salt mixture and POCl₃ (0.78 mL, 8.4 mmol, 1 equiv) was added. After stirring with cooling for 5 min, the mixture was brought to r.t. and stirred for 20 h. The mixture was cooled again in an ice-salt mixture and H₂O (5 mL) was slowly added. Stirring with cooling for 5 min was followed by reaction at r.t. for 25.5 h. The crude mixture was then poured into CH₂Cl₂ (100 mL), washed with three times with dil HCl (1–2%, 100 mL in total), dried (MgSO₄), filtered, and washed with pentane, providing the pure compound as a white solid; yield: 0.49 g (30%); mp 100–102 °C.

Funding Information

The research leading to these results received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 Research and Innovation Program: Grant Agreement 694078 – Solvometallurgy for critical metals (SOLCRIMET).
