Abstract Tris(acetylacetonato) iron(III) [Fe(acac)\textsubscript{3}] is an indispensable reagent in synthetic chemistry. Its applications range from hydrogen atom transfer to cross-coupling reactions and to use as a Lewis acid. Consequently, the exceptional utility of Fe(acac), has been demonstrated in several total syntheses. This short review summarizes the applications of Fe(acac), in methodology and catalysis and highlights its use for the synthesis of medicinally relevant structures and in natural product syntheses.

1 Introduction

Being the fourth most abundant element in the Earth’s crust, iron possesses various redox properties leading to oxidation states from –II to +VI, with the oxidation states +II and +III being the most favored. The role of iron\textsuperscript{1} in synthetic organic chemistry has undergone significant transformation, in particular, its use in homogeneous catalysis has changed the view on iron as a non-noble metal.\textsuperscript{2} For decades, the acetylacetonate salt of iron(III), Fe(acac)\textsubscript{3}, has played a major role in synthetic chemistry. Tris(acetylacetonato) iron(III) is a deep-red crystalline solid with good solubility in alcoholic and chlorinated solvents. Several protocols for the synthesis\textsuperscript{3} and purification\textsuperscript{4} of Fe(acac)\textsubscript{3} are

1 Introduction

Being the fourth most abundant element in the Earth’s crust, iron possesses various redox properties leading to oxidation states from –II to +VI, with the oxidation states +II and +III being the most favored. The role of iron\textsuperscript{1} in synthetic organic chemistry has undergone significant transformation, in particular, its use in homogeneous catalysis has changed the view on iron as a non-noble metal.\textsuperscript{2} For decades, the acetylacetonate salt of iron(III), Fe(acac)\textsubscript{3}, has played a major role in synthetic chemistry. Tris(acetylacetonato) iron(III) is a deep-red crystalline solid with good solubility in alcoholic and chlorinated solvents. Several protocols for the synthesis\textsuperscript{3} and purification\textsuperscript{4} of Fe(acac)\textsubscript{3} are
available in the literature, even videos with practical guidance for laboratory praxis are available on YouTube. Different types of reactions and synthetic procedures have been used and reported over the last decades. The use of Fe(acac)₃ in synthetic organic methodology and natural product total synthesis is fairly broad. In this short review, we will focus on the recent contributions in the fields of radical transformations, hydrogen atom transfers from in situ generated iron hydride species, carbometalations and cross-couplings.

2 Hydrogen Atom Transfer (HAT)

In the recent past, Fe(acac)₃ in combination with well-known reducing agents such as silanes has evolved to be an efficient hydrogen atom donor catalyst for the reductive mediation of radical reactions. In 1989, pioneering work on selective functionalizations of electron-rich or non-activated olefins was published by Mukaiyama working on Co(acac)₂-catalyzed hydration reactions of non-activated olefins. This class of reactions is based on hydrogen atom transfer (most likely H-atom, no hydride or proton transfer) from transition-metal hydride species to electron-rich olefins, and by so doing, generating the desired reactivity for subsequent transformations (Scheme 1). Up to now, feasible reaction partners for HAT-initiated reactions are olefins, Michael acceptors, nitroarenes, sulfonyl hydrazones, heteroarenes and heteroarene N-oxides. Furthermore, radical driven isomerizations and cyclizations of alkene-tethered ketones are reported.

The combination of Fe(acac)₃ and phenylsilane in the presence of an alcoholic solvent at elevated temperatures was described by Baran as the optimal combination for such reductive olefin couplings (Scheme 2). These conditions are compatible with numerous functional groups on the donor olefin and tolerant a variety of electron-withdrawing olefins. This process has been developed for the synthesis of rosthorn A, which is a kaurane diterpenoid, and its synthesis was split into a cyclization phase (selective C–C bond formations) and an oxidation phase (selective C=O bond formation). This reductive olefin coupling now opens inspiring and fascinating possibilities for disconnections during the cyclization phases. The synthesis of decalin was one of the first examples of an intramolecular HAT reaction provided amongst a variety of others in the pivotal paper published by the Baran group (Scheme 2). Moreover, it has been shown that even cyclopropanes can be obtained in excellent yields using the described transformation.

In 2014, Baran and co-workers published reductive olefin couplings of electron-rich donor olefins and electron-deficient acceptor olefins (Scheme 2). These types of reactions are based on HATs onto donor olefins to generate radicals of nucleophilic character to add in a 1,4-addition fashion. This addition to acceptor olefins results in the formation of a new carbon–carbon single bond. The reaction pathway for the addition of nucleophilic radicals to electron-withdrawing olefins was studied with numerous model and deuteration experiments. Baran’s group deconvoluted the role of all the reagents and reaction parameters revealing the importance of an alcoholic solvent.

---

The combination of Fe(acac)₃ and phenylsilane in the presence of an alcoholic solvent at elevated temperatures was described by Baran as the optimal combination for such reductive olefin couplings (Scheme 2). These conditions are compatible with numerous functional groups on the donor olefin and tolerant a variety of electron-withdrawing olefins. This process has been developed for the synthesis of rosthorn A, which is a kaurane diterpenoid, and its synthesis was split into a cyclization phase (selective C–C bond formations) and an oxidation phase (selective C=O bond formation). This reductive olefin coupling now opens inspiring and fascinating possibilities for disconnections during the cyclization phases. The synthesis of decalin was one of the first examples of an intramolecular HAT reaction provided amongst a variety of others in the pivotal paper published by the Baran group (Scheme 2). Moreover, it has been shown that even cyclopropanes can be obtained in excellent yields using the described transformation.
all-carbon quaternary centers, which is still a challenging motif in total synthesis. An important example is the generation of quaternary centers at the D-ring of steroids, in particular in proximity to existing quaternary centers (see compound 13, Scheme 2). In 2016, Shenvi and co-workers published the use of (iPrO)SiPhH3 as an exceptionally mild reductant for metal-catalyzed HATs, which allowed HAT-initiated reactions to be carried out at lower temperatures compared to those used in Baran’s protocol.

The scope of acceptor molecules was broadened by the use of preformed sulfonyl hydrazones. This protocol now allows the formal incorporation of methyl groups. After radical addition, reductive cleavage of the sulfonyl hydrazine residue leads to the corresponding hydromethylation product 17 (Scheme 3, a). Using this protocol, Baran was able to transform citronellol (21) into compound 22 in a single step (Scheme 3, c). Moreover, activity toward the hydroamination of olefins using nitroarenes 18 have been described by the Baran group, with particular dedication to functional group tolerance (Scheme 3, b). A representative example is the synthesis of building block 25, which is useful for applications in medicinal chemistry (Scheme 3, c). Furthermore, Minisci reactions of different substituted heteroarenes 26 and olefins 27 show the power and chemoselectivity of these HAT conditions. In contrast to previously reported HAT conditions, additional Lewis acid activation is required to obtain Minisci products 28 in moderate to good yields (Scheme 3, d). Among the different Lewis acids tested, BF3 proved to provide the highest yields. In this context, Baran and co-workers described the use of pyridine and quinoline N-oxides 29 in combination with additional Lewis acids as being more effective in HAT-based Minisci reactions (Scheme 3, e).

The field of HAT-initiated transformations has been broadened in the recent past. In 2016, Cui and co-workers published an iron-triggered isomerization of α,α-diarylalcoholic alcohols 32 to obtain α-aryl ketones 33 in excellent yields (Scheme 4, a). The reaction proceeds via a 1,2-migration of an aryl radical and subsequent single-electron-initiated oxidation. However, the choice of suitable reaction partners for HAT-driven processes is certainly not limited to intramolecular olefins, heteroatom-substituted alkenes, Michael acceptors, heteroarenes, nitroarenes and sulfonyl hydrazones. The intramolecular addition of nucleophilic radicals to carbonyl groups of any kind has been studied extensively over the years. The use of ketones as acceptors in radical reactions is limited due to its reversibility, which is shown in rate studies that provide slower ring closure of nucleophilic radicals to ketones than the corresponding ring opening of alkoxy radical counterparts. This pathway is well-known as the Beckwith–Dowd ring expansion. Yet, in 2018, the group of Bonjoch and Bradshaw reported on the intramolecular additions of HAT-obtained radicals onto ketone 34 and provided a number of examples in good to very good yields (e.g., Scheme 4, b). The radical cyclization of alkene-tethered ketone 34 provides stable tricyclic alcohol 35. Competition experiments on this reaction pathway in the presence of methyl vinyl ketone show the predominance of the intramolecular cyclization onto the carbonyl group by comparison to the intermolecular reductive olefin coupling with Michael acceptors (Scheme 4, c).

In 2015, Pronin and co-workers published an approach for the construction of the tricyclic framework of paxilline indole diterpenes 39. The key step was a radical-polar crossover polycyclization initiated by Fe(acac)3 and Shen’s’[iPrO)SiPhH3, followed by an aldol addition of the in situ formed iron enolate (Scheme 5, a). Furthermore, this strategy was used to obtain intermediate 41 to accomplish the total synthesis of emindole SB (Scheme 5, b). For the construction of the trans-decalin unit 43 of hispidanin A, the Liu group also used Baran’s HAT-mediated radical polyene-like cyclization strategy (Scheme 5, c).
2015, Carreira and co-workers published the HAT-initiated construction of the core of (±)-hippolachnin A in analogical conditions (Scheme 5, d).16,19

### 3 Oxidations and Radical Transformations

In addition to HAT-initiated reactions, Fe(acac)₃ appears in different types of radical-driven synthetic transformations. For decades, the combination of Fe(acac)₃ and oxidizing agents (such as dioxygen, hydrogen peroxide and organo-hydroperoxides) is known to be able to oxidatively functionalize benzylic and allylic positions,1 as well as aromatic systems and conjugated alkenes.16–19 From a historical point of view, it is pertinent to mention the first experiments using Fe(acac)₃ for the oxidation of cholesterol (Scheme 6, a) and autoxidations of cholesterol (b) by Kimura 1973,16 and autoxidations of cholesterol (b) by Kimura 198318 and (c) in 1982,19 in which β-epoxidation of cholesterol (Scheme 6) by Kimura and co-workers in 198219 and in 198318 using Fe(acac)₃ as the iron catalyst in the presence of either hydrogen peroxide, the iron-catalyzed oxidation effected selective β-epoxidation of cholesterol (46) in 68% yield. This reaction has been investigated to provide a model reaction for biological oxofunctionalizations of steroid skeletons.16 Moreover, extensive studies toward biological oxidations of liposomal cholesterol (46) have been described by Kimura and co-workers in 198219 and in 198318 using Fe(acac)₃ as the iron catalyst in the presence of either egg lecithin or unsaturated long-chain fatty acids such as oleic acid (Scheme 6). Oxidation mixtures tend to give compositions of various oxidized products 47–53 with overall moderate to decent conversions (Scheme 6, b and c).18,19

**Scheme 6** (a) Historical overview of β-epoxidation of cholesterol by Kimura 1973,16 and autoxidations of cholesterol (b) by Kimura 198318 and (c) in 1982,19
However, in this work by Kimura, Fe(acac)$_3$ in the presence of oxidizing agents was the origin for further iron-based oxidations in a wide variety of substrates. More recently, several methods for the oxidation of benzylic alcohols and benzylic positions have been published (Scheme 7). In 1996, Nobile, Lopez and co-workers demonstrated the aerobic oxidation of α-hydroxy aryl ketones 54 to obtain symmetrically substituted 1,2-diketones 55 in good to excellent yields using catalytic amounts of Fe(acac)$_3$, dioxygen and a sacrificial aldehyde, albeit the substrate scope was limited to aromatic substituents (Scheme 7, a). Further dehydrogenations with catalytic amounts of Fe(acac)$_3$ in the presence of potassium carbonate and 1,10-phenanthroline to obtain aryl ketones 57 were performed by the Hong group in 2014 (Scheme 7, b). The advantage of this methodology is the absence of sacrificial reagents for hydrogen acceptance. However, the oxidation only proceed with secondary alcohols in benzylic positions (Scheme 7, c). A similar type of reaction is the introduction of organo peroxides at benzylic, allylic or propargylic ether positions. In 2012, Urabe reported the synthesis of tert-butyl peroxyacetals 58 starting from the corresponding ethers 59 by applying Fe(acac)$_3$ in catalytic amounts with an excess of tert-butyl hydroperoxide in toluene (Scheme 7, c). The corresponding peroxyacetals 60 (further examples: 61, 63, 65, 67 and others) were obtained in excellent yields. In 1999, Blanco and co-workers described an oxidative rearrangement of bicyclo[n.1.0]alkan-1-ols 68 with a reagent mixture of catalytic amounts of Fe(acac)$_3$, silica gel, and dioxygen under irradiation (100 W domestic light bulb) to obtain the corresponding β-hydroperoxy cyclohexanones 69 in decent yields (Scheme 7, d). By prolonging the reaction time from three to 36 hours, in the case of cyclopropane 70, a subsequent ring closure yielding the corresponding peroxyacetal 71 was observed (Scheme 7, d).

Furthermore, Pan and co-workers published an alkylation of cyclic ethers 73 using Fe(acac)$_3$ and DTBP as a radical starter. This reaction proceeds via a radical decarboxylative sp$^2$–sp$^3$ coupling and afforded alkenylated dioxanes 74, pyrans and tetrahydrofurans in good yields (Scheme 8, a). The same group reported the use of cycloalkanes, e.g., cyclopentane, cyclohexane (76), cycloheptane etc., for the decarboxylative alkylation and obtained the corresponding alkenylated cycloalkanes 77 in moderate to very good yields (Scheme 8, b).

In 2016, Patel and co-workers reported the selective functionalization of the C-3 position in flavones 78 by using catalytic amounts of Fe(acac)$_3$, potassium persulfate, DABCO and either tert-butyl peroxybenzoate for the introduction of a single methyl group, or cycloalkynes or formamides for the introduction of a cycloalkyl residue or formyl group at elevated temperatures (Scheme 8, c).

4 Synthesis and Use of Alkynes and Allenes

Numerous applications of iron in the context of alkyne chemistry varying from alkyne synthesis to selective addition and annulations have been published in the recent
past. In 2015, Fürstner reported a new method for the synthesis of non-terminal alkynes by placing Fe(acac)₃ and methylithium. The method provides a broad scope of methylated alkynes in yields of up to 95% (Scheme 9, a). This strategy was applied to the synthesis of fragment 86 in Fürstner’s total synthesis of tulearins A and C (Scheme 9, b).²⁷

When it comes to the use of alkynes as starting materials, Bäckvall’s group published the synthesis of substituted allenes 88 starting from propargylic acetates 87 (Scheme 8, a).²⁸ Bäckvall and Kessler utilized a large substrate scope obtaining good to excellent yields of the allene products. The reaction proceeds via an iron-catalyzed cross-coupling mechanism. Earlier, Fürstner introduced examples for the synthesis of substituted allenes 90 starting either from propargylic epoxides 89 or propargylic cyclopropanes 91 bearing a geminal diester on the cyclopropane core (Scheme 10, b and c). A convenient example from natural product total synthesis is Fürstner’s Fe(acac)₃-catalyzed method to convert propargylic epoxide 93 into the corresponding trisubstituted allene 94 in 62% yield and good diastereoselectivity en route toward amphidinolide Y (Scheme 10, d).³¹

A broader field in the use of Fe(acac)₃ in alkyne chemistry is the benzannulation of aryl compounds. In 2011, Nakamura reported a [4+2] benzannulation between biaryl or 2-alkenylphenyl Grignard reagents 96 and alkynes 95 for the synthesis of polyaromatic compounds 97 (Scheme 11, a).²² The scope is limited to aryl Grignard reagents but a variety of variations on alkynes 95 are possible. Optimized reaction conditions use catalytic amounts of Fe(acac)₃ and dtbpy as the ligand in the presence of 1,2-dichloro-iso-butane as oxidant, which was required to prevent partial polymerization of the alkyne. The use of aminoquinoline carboxamides 98 established the possibility to perform directed iron-catalyzed C–H bond activation, which was reported by Nakamura for the preparation of disubstituted indenes 99 in moderate to very good yields (Scheme 11, b).³¹
Carbometalations\(^{34}\) of alkynes represent a highly stereo and regioselective tool for the synthesis of higher functionalized and tetrasubstituted olefins. Examples using catalytic amounts of Fe(acac)\(_3\) for syn-carbometalations are discussed below (Scheme 12). In 2001, Hosomi and co-workers published a carbolithiation of internal alkynes \(^{100}\) for the synthesis of higher substituted olefins \(^{101}\) and the possibility of trapping vinylmagnesium compounds with different electrophiles (e.g., H\(^+\), D\(^+\), ZnCl\(_2\)/NBS, aldehydes, CuCN/2LiCl/allyl bromide) (Scheme 12, e).\(^{38}\) This carbomagnesiation procedure was applied by the Ma group for an alkyne methylation to obtain \(^{102}\) and \(^{105}\) in very good yields and E:Z ratios (Scheme 12, b and c). In 2007, Ma and co-workers reported the regio and stereoselective addition of Grignard reagents to 2,3-allenoates \(^{106}\) for the synthesis of \(\beta,\gamma\)-unsaturated trisubstituted olefins \(^{107}\) (Scheme 12, d).\(^{39}\) Carbometalations of propargylic and homopropargylic alcohols \(^{108}\) with Grignard reagents have been reported by Ready with broad substrate scope and the possibility of trapping vinylmagnesium compounds with different electrophiles (e.g., H\(^+\), D\(^+\), ZnCl\(_2\)/NBS, aldehydes, CuCN/2LiCl/allyl bromide) (Scheme 12, e).\(^{39}\) This carbomagnesiation procedure was applied by the Ma group for an alkyne methylation to obtain \(^{111}\) for the total synthesis of leucosceptroids A and B (Scheme 12, f).\(^{40}\)

5 Cross-Couplings and Cycloisomerizations

Cross-coupling reactions have become irreplaceable tools for the synthesis of C–C bonds at sp, sp\(^2\) and sp\(^3\) hybridized carbon atoms bearing a wide range of residues on both sides of the reaction partners. One of the first described approaches using palladium or nickel as metals for this kind of transformation was the coupling of Grignard reagents with aryl or vinyl halides by Kumada and co-workers.\(^{41}\) As far back as 1941, the first Fe-catalyzed cross-cou-
pling was reported by Fields and Kharash, the value of which only became apparent a few decades later.\textsuperscript{42} The substrate scope of Fe-catalyzed cross-coupling reactions is extremely broad since aliphatic substrates are also compatible with this method. Therefore, it is an even more powerful C–C bond-forming reaction compared to the corresponding Pd-catalyzed transformations (Scheme 13).

Oxidations states ranging from Fe(–II) up to Fe(III) species are proposed to be involved in the catalytic cycle depending on the type of cross-coupling. In most cases the initial step is the in situ reduction of Fe(acac)\(_3\) to a low valent iron species. The different mechanisms are reviewed elsewhere.\textsuperscript{43,44} Even though reactive intermediates are difficult to characterize experimentally, the formation of the intermediary ate-complexes was at least confirmed by the group of Koszinowski who found evidence for Fe(III), Fe(II) and Fe(I) species via electrospray ionization mass spectrometry. Further investigations suggested that product formation occurred from a \([\text{Ph}_3\text{Fe}^{II}\text{IPr}]^+\) complex (in the case of a PhMgBr to iPrCl coupling) to give \([\text{Ph}_2\text{Fe}(I)]^+\) and \(\text{PhIPr}\) as the desired product.\textsuperscript{45}

### 5.1 Fe-Catalyzed sp\(^2\)–sp\(^2\) Cross-Coupling Reactions

Transition-metal-catalyzed sp\(^2\)–sp\(^2\) cross-coupling reactions were first reported by Julia and co-workers. They investigated the reaction between tert-butyl sulfones with phenylmagnesium bromide using different metal acetacetonates (Scheme 14, a).\textsuperscript{46a} In contrast, Knochel and co-workers used either aromatic Grignard reagents or the corresponding cuprates in cross-coupling reactions with vinyl halides or sulfonyl enols. These conditions were even compatible with intramolecular ester moieties on the organometallic reagent (Scheme 14, a).\textsuperscript{46b,c} On the other hand, Fields and Kharash, the value of which only became apparent a few decades later.\textsuperscript{42} The substrate scope of Fe-catalyzed cross-couplings in synthetic chemistry, only selected examples will be mentioned briefly. The group of Li used a sp\(^2\)–sp\(^2\) cross-coupling between 2,4-F\(_2\)C\(_6\)H\(_4\)MgBr and vinyl chloride \textsuperscript{119} to construct the carbon skeleton of the eastern fragment \textsuperscript{120} of posaconazole in 76% yield (Scheme 14, c).\textsuperscript{48}

Sweeney and co-workers were able to establish a tandem Heck–Kumada cross-coupling reaction to construct dihydrofuran \textsuperscript{122} in high yield and diastereoselectivity.\textsuperscript{49} The stereochemical outcome can be rationalized by the disfavored steric interactions of the iron residue and the C–H bond at the ortho position of the aromatic ring (Scheme 15).

### 5.2 Fe-Catalyzed sp\(^2\)–sp\(^3\) Cross-Coupling Reactions

Fe-catalyzed sp\(^2\)–sp\(^3\) (electrophile–nucleophile) cross-couplings offer the advantage of not undergoing β-hydride eliminations in contrast to palladium-catalyzed cross-couplings. The use of aliphatic Grignard reagents requires NMP as a co-solvent. It is proposed to be essential for the formation of the \([\text{Mg(NMP)}_3][\text{FeMe}_3]\) complex, which is pivotal for high selectivities using aliphatic Grignard reagents.\textsuperscript{50} The cross-coupling of vinyl or aryl electrophiles with aliphatic Grignards tolerates a wide variety of functional groups such as different electron-withdrawing or electron-donating groups on the electrophile. Furthermore, ester moieties are also compatible with these organometallic species. Thus, electrophiles such as Cl, Br, I, OTs, OTf, SePh, TePh and NMe\(_3\)OTf can be employed in Fe(acac)\(_3\)-mediated cross-couplings, delivering the desired products in good to
high yields and good diastereoselectivities (Scheme 16, a).4,5,51 Furthermore, even more complex substrates exhibiting polyaromatic, bridgehead, allyl amine or vinyl alkylnyl motifs are also compatible with this methodology. In particular, tosyI-substituted Michael acceptors such as 125 can be joined to aliphatic residues to give access to highly substituted double bonds with excellent control of the double bond geometries (Scheme 16, b).52 Moreover, the use of enol phosphonates 127 was reported by the Habiaik and Gagger groups. These substrates can easily be synthesized from the corresponding ketones and are easier to handle on large scale compared to their corresponding triflates.53 In continuation of their contribution on these enol phosphonates, the substrate scope could be enlarged to conjugated phosphonate dienes (Scheme 16, c).53 As Fe(acac)3-catalyzed cross-couplings tolerate a large variety of functional groups, Marquais and co-workers used manganese instead of Grignard nucleophiles to broaden the substrate scope to ketones (Scheme 16, d).54 In addition, the tolerance of Grignard reagents to ketones was reported by Cahiez in 2009.54b Besides coupling to carbon residues, Fe(acac)3 and tBuMgCl can be used for dehalogenation. The proposed mechanism involves hydride transfer from the tBu group to the Fe-arene species, which then undergoes reductive elimination (Scheme 16, e).55 The application of Fe(acac)3-mediated sp3–sp2 cross-couplings in total synthesis was, amongst others,1,56 demonstrated by the Kirschning group in their total synthesis of noricumazol A. The Fe(acac)3-catalyzed cross-coupling for the synthesis of the eastern fragment 135 in an excellent yield (Scheme 16, f).57

5.3 Fe-Catalyzed sp3–sp2 Cross-Coupling Reactions

Fe-catalyzed sp3–sp2 cross-couplings of aromatic Grignard reagents to primary or secondary electrophiles make use of a large variety of substrates. Cyclic or linear aliphatic starting materials as well as halogenated azetidines deliver good to excellent yields in cross-coupling reactions.58 The use of thioethers as electrophiles in cross-coupling reactions has been described by Denmark and co-workers using phenyl and pyridinyl thioethers or sulfones (Scheme 17, a).59 Furthermore, modified Suzuki59 cross-coupling reactions have been reported by the Bedford group.60 They used tBuLi to activate the boron species as its ate-complex, followed by Lewis acid activated C–C bond formation (Scheme 17, b).61 Nakamura and co-workers developed a protocol for the sp3–sp2 Negishi61a coupling with substrates bearing esters or nitriles on the aliphatic side chain (Scheme 17, b).61b Hu’s group developed conditions for coupling CF2H groups to organozinc or magnesium compounds, while Zhang and co-workers reported a Pd-Fe co-catalyzed coupling of CF2H groups involving a CF2 carbene intermediate (Scheme 17, c).62,63 Beginning with benzaldehyde, Leino designed an in situ reduction of a carbonyl group to its corresponding chloride followed by coupling to the second aryl unit (Scheme 17, d).64 The introduction of chirality toward the sp3-hybridized C-atom was first accomplished in an Fe(acac)3-mediated cross-coupling by Nakamura in 2015.43e Originating from racemic α-chloro ester 148 the enantioenriched coupling product 151 was obtained in an enantio- meric ratio (e.r.) of 87:13 and 75% yield. This transformation was most effective with R2 being a methyl group (Scheme 17, e). Further cleavage of the theptyl ester delivers free acid dexasibuprofen (152), which can be co-crystallized with octylamine to enhance the e.r. up to >99:1.43e

HMTA = hexamethylenetetramine, TMEDA = tetramethylethylenediamine.
5.4 Fe-Catalyzed \( \text{sp}^3-\text{sp}^3 \) Cross-Coupling Reactions

Fe-catalyzed \( \text{sp}^3-\text{sp}^3 \) cross-couplings are not as widespread as \( \text{sp}^2-\text{sp}^3 \) cross-coupling reactions. On the other hand, they possess high potential for the installation of C–C bonds at \( \text{sp}^3 \)-hybridized positions of complex molecules.

Nakamura and co-workers used in situ hydroboration of terminal olefins followed by formation of the isopropylmagnesium bromide ate complex 154 to couple these activated boron nucleophiles to aliphatic halides.43d It should be mentioned that this transformation is also compatible with functional groups such as nitriles or esters (Scheme 18, a). Fürstner and co-workers applied Fe(acac)\(_3\) cross-couplings to tosylated alkynyl cyclopropanes 156.65 Their protocol provided all-carbon quaternary centers in good to excellent yields, whilst tolerating synthetically useful functional groups (Scheme 18, b).

5.5 Fe-Catalyzed Cross-Coupling Reactions at \( \text{sp} \) Centers

Similar to \( \text{sp}^3-\text{sp}^3 \) cross-couplings, transformations at \( \text{sp} \)-hybridized carbons are a remaining challenge. In this context, Meng and co-workers developed conditions for the homo-Glaser reaction of alkyne 158 with Fe(acac)\(_3\) and Cu(acac)\(_2\) as the co-catalyst (Scheme 19, a).66 Furthermore, not only are \( \text{sp}-\text{sp}^3 \) couplings possible, but also combinations with \( \text{sp}^2-\text{sp}^3 \) hybridized halides. The nucleophilic alkyne 160 was activated by decarboxylation or direct C–H oxidation at 140 °C (Scheme 19, b).67

In the context of Fe(acac)\(_3\)-catalyzed heteroarene syntheses there are only a limited number of methodology reports. However, there are numerous applications in total syntheses. Many of these have been summarized by Szostak and co-workers.39 A selected variety of Fe(acac)\(_3\)-catalyzed cross-coupling reactions are illustrated in Scheme 20 (a). In most cases, chlorides are used to provide good selectivities for the cross-coupling reactions as the carbon–chlorine bond is the preferred site for Fe insertion.48b,c,51e,68 Furthermore, nitrogen-directed cross-coupling of heteroarenes can be performed regiospecifically under mild conditions. The
substrate scope for generating tetrasubstituted pyrimidines 164 could be further extended by using tosylates or halides as coupling partners (Schemes 20, b and c).69,70 One example of how far this methodology can be extended was described by the group of Lee in their synthesis of SGLT2 inhibitor 170.71 They employed a sp2–sp3 cross-coupling reaction to compensate for the omitted functional group, an external C–H bonds partially simplifies this classical approach. To regiospecifically functionalize groups at specific positions to generate the new C–C bond (Scheme 21, b).73 Interestingly, if an acetylated oxime is in proximity to the ortho-position N-arylation takes place (Scheme 21, c).74 Besides aromatic substrates, the methodology was expanded to unsaturated amides. An additional ortho directing group (ODG) attached to the nitrogen is essential for coordinating the iron catalyst. This in turn is pivotal for the regioselective C–H activation and for controlling the double bond geometry (Scheme 21, d).75 Vishwakarma and co-workers reported Fe(acac)3-catalyzed Suzuki cross-coupling reactions of aryl boronic acids to pyrazine C–H bonds instead of C–halide bonds. This method was used for the installation of the aryl–pyrazine bond in the synthesis of botryllazine A (Scheme 21, e).76

5.7 Fe-Catalyzed Ullmann Coupling Reactions

Applications in the Ullmann coupling for the construction of biaryl ethers in excellent yields were published by

![Diagram](image-url)
the Zhang group, who used a copper–iron co-catalyst system (Scheme 22, a). Further investigations led to double Ullmann reactions with 1,4-diiodo arenes, which can also be expanded to macrocyclizations of polyarylethers, parallel to their work on biaryl ethers, Nakamura and co-workers investigated the coupling of primary aryl amines which were converted into the zincate and subsequently used for secondary amine formation (Scheme 22, b).

5.8 Fe-Catalyzed Cross-Coupling of Acyl Chlorides

Earlier, in 1984, Ronzini and co-workers described the Fe(acac)3-catalyzed cross-coupling of acyl chlorides to aliphatic or aromatic Grignard reagents (Scheme 23, a) and this research was later continued by the Fürstner group. The Dong group used Fe(acac)3 for the regio- and site-selective acylation of diols and carbohydrates (Scheme 23, b). The reagents of choice were the corresponding acyl chloride, Hünig’s base and catalytic amounts of Fe(acac)3, which afforded the corresponding selectively activated acyl chlorides for the synthesis of silyl chlorides.

5.9 Fe-Catalyzed Allylations

The Fe-catalyzed allylation of either aromatic or aliphatic Grignard reagents is possible by using allyl ethers or sulfonfyl chlorides as electrophiles (Scheme 24, a). Furthermore, the direct functionalization of allylic C–H bonds was reported by Nakamura and co-workers, which was also applicable to different substitution patterns on the allylic reagent (Scheme 24, b).

5.10 Miscellaneous Fe-Catalyzed Cross-Coupling Reactions

Further applications using Fe(acac)3 were reported by Fürstner as a highly diastereoselective method for simultaneous ring-opening of 2-pyrones (Scheme 25, a). This transformation is mechanistically proposed as 1,6-addition and reversion with the carboxylate as the leaving group. Furthermore, this strategy was used for the installation of the Z/E diene moiety of granulatamide B in >10:1 d.r. (Scheme 25, b). Fürstner and Echeverria developed further reaction types of low-valent iron generated from Fe(III), where the iron reacts in a metallaa-Alder-ene fashion with the ene–yne system to form metallacycle I (Scheme 25, c). Instead of a direct reductive elimination, the addition of Grignard reagents opens the five-membered ring followed by reductive elimination of Fe(I) to build up the tetrasubstituted double bond of 202. The Nakamura group developed a protocol for insertion of iron into phenyl-iodo bonds followed by 1,5-HAT (Scheme 25, d). The so-generated organoiron intermediate behaves similarly to established sp2–sp3 couplings. Overall, this transformation allows access to α-functionalized pyrrolidines.

Devroy and co-workers used Fe-bpy, which was prepared from Fe(acac)3 in situ and investigated the 4×4 cycloisomerization of dienes with allyl ethers (Scheme 26). This transformation was also applied intramolecularly for amine- or ether-tethered substrates to give the corresponding trans-fused six-membered rings 206.
6 Borylations

Besides the tremendously broad field of Fe(acac)₃-mediated cross-couplings, borylations of alkyl or aryl halides have been reported in the literature. In 2014, Cook and co-workers published the borylation of various alkyl halides with bispinacolato diboron and provided a very broad scope of substrates (Scheme 27, a). The electrophiles of choice were chlorides, bromides, iodides and tosylates, with bromides giving the best results in up to 95% yield. Borylations of aryl chlorides were reported by Nakamura in 2017 using bispinacolato borane in yields up to 71% (Scheme 27, b). Coupling of pinacolato borane with aryl bromides using iron–copper catalysis has been described by Chavant in yields of up to 81% (Scheme 27, c).

In 2017 Findlater and Tamang showed that it was possible to obtain the corresponding alcohol through the Fe-catalyzed hydroboration of aldehydes or ketones. It is proposed that this reaction proceeds via alkoxyboron species, which delivers alcohol under standard work-up conditions (Scheme 28).

7 Miscellaneous Reactions

Additional transformations highlight the great potential of Fe(acac)₃ catalysis and synthesis. The Kirihara group published a selective and efficient method for dithioacetalsization of 2-silylated 1,3-dithianes. In these transformations the use of Fe(acac)₃ in combination with NaI and hydrogen peroxide greatly improves the yields of the corresponding acyl silanes compared to other well-established protocols (Scheme 29, a). The same conditions were applied for oxidative cleavage of aryl-, vinyl-, and alkyl-substituted dithianes in up to quantitative yields (Scheme 29, b).
A tremendously broad scope of substrates for transesterifications of different alcohols with different esters was described by Weng and co-workers in 2011 (Scheme 30, a). An approach toward the diversity-oriented ketodiol 226 via didecarboxylative bidirectional aldolization of diacid 224 was published by Rodriguez (Scheme 30, b). A different type of reaction is the intermolecular heterocoupling of enolates described by the Baran group to synthesize the corresponding 1,4-diketones 229 (Scheme 30, c). The mechanism is proposed to proceed via an oxidative radical phenol coupling type mechanism. Further, Hayashi and Sasaki published a pinacol coupling of aryl ketone 230 with a phenyltinanium reagent in the presence of Fe(acac)₃ to afford the corresponding pinacol 231 (Scheme 30, d). The initial step is a reductive cross-coupling of the phenyl substituent to generate a low-valent titanium species. This titanium species subsequently catalyzes the pinacol coupling.

An additional variation to carbometalations of alkynes and allenes is the hydromagnesiation of olefins. Subsequent addition of carbon dioxide generates the corresponding carboxylic acids. This was applied by Thomas and co-workers to the synthesis of ibuprofen rac-(±) (Scheme 31, a). (±)-Baclophen and (±)-ropipram were synthesized due to their pharmacological relevance via an Fe(acac)₃-mediated Michael addition of nitromethane to α-cyano cinnamic ester 234 (Scheme 31, b). A rather mild approach for the reduction of nitroarenes 235 with different substitution patterns to the corresponding anilines 236 was published by Lemaire and co-workers in 2010 (Scheme 32). This iron-mediated reduction in the presence of TMDS tolerates various functional groups, such as esters, aldehydes, carboxylic acids, bromides, etc., and affords the corresponding anilines 237 as the hydrochloride salts in excellent yields (Scheme 32, a). In 2018, Gennari and co-workers published an asymmetric reduction of imine 237 using a modified chiral Knölker-type catalyst and obtained, in the presence of Fe(acac)₃, high conversions with moderate selectivities (Scheme 32, b). Another Fe(acac)₃-mediated reaction is Bolm’s imination of sulfoxide 239 which proceeds with complete retention of configuration at the sulfur center and affords sulfoximines 240 in very good yields (Scheme 32, c). The same transformation is applicable to sulfides and provides sulfimines in very good yields (Scheme 32, c).

The synthesis of several heterocyclic structures has been shown in the field of Fe(acac)₃-mediated synthetic chemistry. In 2010, Yoon and Williamson published a synthesis of 3-amido-oxindole 241 (Scheme 32, a). This aminohydroxylation strategy was applied to sulfimines 240 in very good yields (Scheme 32, c). The same transformation is applicable to sulfides and provides sulfimines in very good yields (Scheme 32, c).

Fe(acac)₃-mediated reaction is Bolm’s imination of sulfoxide 239 which proceeds with complete retention of configuration at the sulfur center and affords sulfoximines 240 in very good yields (Scheme 32, c).

The synthesis of several heterocyclic structures has been shown in the field of Fe(acac)₃-mediated synthetic chemistry. In 2010, Yoon and Williamson published a synthetic access to 1,3-oxazolidines 243 by aminohydroxylation of olefins 242 using N-sulfonyl oxaziridines (Scheme 33, a). This aminohydroxylation strategy was applied to the synthesis of (±)-octopamine. Bao employed radical conditions for the synthesis of 3-amido-oxindole 246 from
aromatic i-propenylamides 244 and γ-butyrolactam 242 (Scheme 33, b). Furthermore, Prins cyclizations of homopropargylic alcohols and amines 247 were reported by Padrón and co-workers (Scheme 33, c). By using aldehydes in combination with TMSI the iodinated unsaturated heterocycle 248 was obtained. A very different example is the synthesis of benzo[b][thiophenes 250 by Che in 2011. They demonstrated that Fe(acac)₃ is not only the catalyst but also the source of acetylacetone as the reagent. Therefore, one ligand on the iron is exchanged by thiosaliclycic acid 249 and thus liberates acetylacetone for the subsequent transformation (Scheme 33).

8 Conclusions

Even though Fe(acac)₃ is broadly applicable in organic synthesis, a large variety of improvements are observed in the area of cross-coupling reactions. The remarkable functional group tolerance as well as its applicability to alkyl reagents illustrates the significance of Fe(acac)-catalyzed cross-coupling reactions. Additionally, the field of HAT-initiated transformations enables new pathways to complex natural products. Considering the relatively young area of this research, one can anticipate even more relevant contributions in the future.
