Institute of Digestive and Hepatoboliary Sciences, Medanta The Medicity, ¹Department of Pathology, Medanta The Medicity, Gurugram, Haryana, India Tissue acquisition from mediastinum is difficult due to anatomic location and presence of vessels. Endoscopic ultrasound provides access to difficult mediastinal locations that are near esophagus. We describe a case of pericardial lesion, endoscopic ultrasound guided guided fine needle aspiration cytology was done and the lesion proved to be metastatic in nature.

Keywords: Endoscopic ultrasound, fine-needle aspiration, metastasis, pericardium

INTRODUCTION

The conventional approaches of tissue acquisition from mediastinum are CT guided fine needle aspiration (FNA) or mediastinoscopy which is invasive. As EUS scope remains in esophagus, it provides access to mediastinum from proximity and vessels are avoided easily. It has been proved to be very safe and accurate for diagnosis of mediastinal lesions that are visible from esophagus. We present a case of EUS guided FNA from pericardial lesion.

CASE REPORT

138

A 34-year-old female had mastectomy followed by chemotherapy for carcinoma breast in 2006. She had local axillary recurrence after 2 years after surgery for which she received chemotherapy. She complained back pain in 2011 and was diagnosed to have lytic spinal lesions in 2011 for which she received radiotherapy and was on kept on hormonal therapy. She was doing well. A surveillance positron-emission tomography-computed tomography in 2016 showed posterior pericardial lesion (near left atrium) measuring $3.2 \text{ cm} \times 1.6 \text{ cm}$ as shown in Figure 1. An endoscopic ultrasound (EUS) done which showed irregularly thickened was pericardium with encasing of a pulmonary vein as shown in Figures 2 and 3. EUS-guided fine needle aspiration (FNA) was done from pericardial thickening with 25 G needle [Figure 4], a total of 2 passes were

made, and on-site cytopathologist was kept to avoid unnecessary FNA passes. The aspirate was positive for malignant cells as shown in Figure 5.

DISCUSSION

The malignant lesions of heart are rare. In an autopsy series of 12,485 cases, malignant lesions of heart were present in 1.23%.^[1] In autopsies with a known malignancy, the cardiac involvement is seen in approximately 10% of cases.^[2,3] The common tumors with metastatic cardiac involvement in females are lungs, lymphoma, and breast.^[1] Carcinoma breast appearing as cardiac metastasis after a long time of mastectomy is

reported.^[4] Use of EUS-guided FNA has been described for pericardial lesion.^[5] EUS is ideal method for FNA of such pericardial lesions as echoendoscope is placed in esophagus (proximity to target lesion), real-time monitoring of FNA procedure is possible, and it provides option of Doppler to avoid vascular structures.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/ her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.
